Measurement Speed - Quicker than a nuclear density gauge!

When speed, confidence, and productivity matter, TransTech Systems, Inc. gives construction teams a clear advantage. As a leader in non-nuclear density measurement, TransTech Systems delivers gauges that are significantly faster than nuclear density gauges, helping crews capture more readings across more of the mat or lift. With the PQI 380+ and SDG 200, operators can verify uniform compaction faster and with greater confidence that required density or compaction levels are being met.

Nuclear density gauge manuals recommend one-minute measurements for the most accurate results, yet many operators shorten test times just to keep projects moving. **That shortcut can compromise accuracy and still may not match the speed of TransTech Systems gauges.** The PQI 380+ delivers accurate, repeatable asphalt readings in less than three seconds, while the SDG 200 provides soil results in 15 seconds. For quality control technicians, that means faster decisions between breakdown or finish roller passes on asphalt paving jobs, and quicker verification between vibratory and static roller passes during soil compaction. Utilizing the faster non-nuclear density meters on a construction project significantly improves the quality control of the materials being laid and compacted.

The result is a faster, safer, and more productive testing process, backed by the accuracy crews need to keep work moving and reduce uncertainty in the field.

It is no surprise that many former nuclear gauge owners and operators are making the switch to TransTech Systems non-nuclear gauges.
